PANM 15

June 6 - 11, 2010, Dolní Maxov, Czech Republic

Standard steps:

- 1 Solve on the coarse mesh.
- 2 Calculate a local error estimate for every element.
- 3 Identify elements with largest errors.
- 4 Refine those elements.
- 5 Go To 1.

Sometimes it Works

Figure: Stationary diffusion of neutrons.

Also Here It Works

Figure: Small deformations of a bookshelf bracket.

But Not All Problems Are Elliptic

Figure: Microwave heating (Maxwell).

Figure: Incompressible flow.

Figure: Oscillations in a Bose-Einstein condensate.

Non-Local Error

Small error
in an element

may cause a large
error elsewhere
in the domain.

Standard Algorithm Fails

Standard steps:

- 1 Solve on the coarse mesh.
- 2 Calculate a local error estimate for every element.
- 3 Identify elements with largest errors.
- 4 Refine those elements.
- 5 Go To 1.

Standard Algorithm Fails

Standard steps:

- 1 Solve on the coarse mesh.
- 2 Calculate a local error estimate for every element.
- 3 Identify elements with largest errors.
- 4 Refine those elements.
- 5 Go To 1.

The error will not decrease!

Unfortunately, most a-posteriori error estimates are *local*:

- Analytical error estimates.
- Solution of local Neumann or Dirichlet problems.
- Gradient recovery techniques.
- Etc.

Dual (Adjoint) Problem

- 1 Linear functional (quantity of interest): $L \in V'$
- 2 Continuous problem: $b(u, v) = I(v)$
- 3 Discrete problem: $b(u_{h,p}, v_{h,p}) = I(v_{h,p})$
- 4 Residual: $r \in V'$ such that $r(v) = I(v) - b(u_{h,p}, v)$
- 5 Relate the residual to the error in the quantity of interest:
Find $G \in V''$ such that $G(r) = L(e_{h,p})$
- 6 By reflexivity: $G(r) = r(\hat{v})$ where $\hat{v} \in V$
- 7 But $L(e_{h,p}) = r(\hat{v}) = I(\hat{v}) - b(u_{h,p}, \hat{v}) = b(u, \hat{v}) - b(u_{h,p}, \hat{v}) = b(e_{h,p}, \hat{v})$
- 8 Dual problem:
Find $\hat{v} \in V$ such that $b(e_{h,p}, \hat{v}) = L(e_{h,p})$ for all $e_{h,p} \in V$

Disadvantage: **Linearity**.

Looking for an Alternative

Requirements:

- 1 Has to identify **sources** of error.
- 2 Has to work well for nonlinear problems.
- 3 Has to be PDE independent.
- 4 Has to be fast.

Looking for an Alternative

Requirements:

- 1 Has to identify **sources** of error.
- 2 Has to work well for nonlinear problems.
- 3 Has to be PDE independent.
- 4 Has to be fast.

Fast Trial Refinements (FTR):

Local refinement + fast global solve.

Jacobian-Free Newton-Krylov (JFNK) Method:

- Discrete problem (linear or nonlinear): $F(Y) = 0$.
- Newton's method:

$$J(Y^n)\delta Y^{n+1} = -F(Y^n).$$

- Finite difference approximation:

$$J(Y^n)v \approx \frac{F(Y^n + \epsilon v)}{\epsilon}.$$

- To be used with an iterative method such as GMRES.
- Coarse mesh approximation is an excellent initial guess.

No matrix assembled, no matrix problem solved.

Example I

Equation $-u''(x) = f(x)$ in $(-\pi, \pi)$, zero Dirichlet BC.

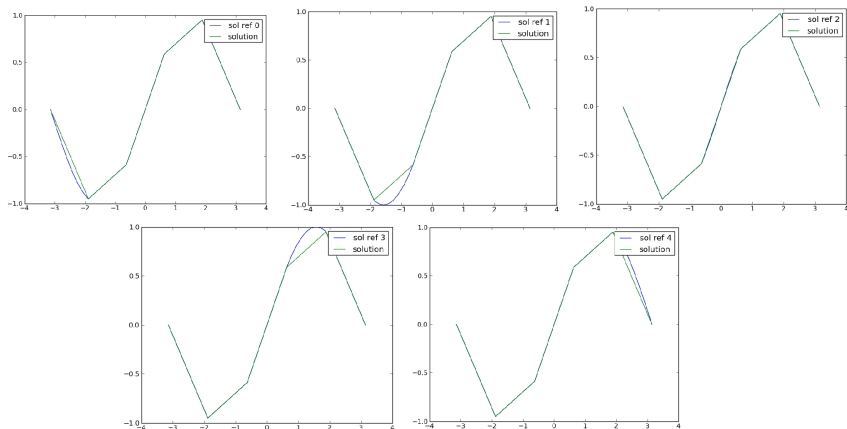

Exact solution $u(x) = \sin(x)$.

Computation goal: $L(u) = u(0.9\pi)$.

Example I

Reference solutions:

Example I

Convergence graphs:

Example II

Equation $-u''(x) = f(x)$ in $(0, 1)$, Dirichlet BC.

Exact solution $u(x) = x^{1/3+0.01}$.

Computation goal: $L(u) = u(0.9)$.

Example II

Convergence graphs:
